RESEARCH GOAL

The aim of this research is to understand the behavior and motivations of blood donors in emergencies, identify the problems and gaps they face during the search for blood types, and study the mechanism of communication between hospitals and blood banks with the community to ensure that critical needs are met as quickly and efficiently as possible.

TARGET SEGMENTS

The "Shariyan" project serves three main segments that you should consider:

Segment 1: Blood Donors: Young adults (aged 18-45) interested in humanitarian work, who own smartphones and move around the geographical area surrounding hospitals.

Segment 2: Seekers/Patients' Families: Individuals facing a sudden critical health condition affecting a relative who are desperately seeking a specific or rare blood type under stress and anxiety.

Segment 3: Medical Institutions (Hospitals & Blood Banks): Emergency staff and blood bank officials who need to update their stock levels and submit immediate requests for assistance without wasting time on traditional communication methods.

USER PROBLEM

Randomness and loss of time: The current reliance on social media (Facebook, WhatsApp) lacks organization; Good news may reach people outside the governorate or after it is too late.

Donor's fear of repeat unsafe donation: The donor does not know the exact date when he is medically allowed to donate again (absence of a digital record).

People's ignorance of where the actual need is: Many people want to donate but do not know which blood bank is currently suffering from a severe shortage of their type.

Psychological stress and tension: Patients' families experience a very bad and panic-filled user experience during the chaotic search.

INSIGHTS

People have a very strong desire to help and provide humanitarian support, but the "availability and accessibility" factor is what prevents them (if they knew there was a hospital five minutes away that urgently needed their blood type, they would go).

Recognition and a gamified system, such as badges and agreements with pharmacies, create a sustainable and ongoing community of donors, not just a one-time donation that ends.

Digitizing data and displaying it on a live map significantly reduces stress levels for patients' families because they feel there is a clear plan of action.

THE 5WS

1

Who

Patients in need of urgent blood transfusions, their families, and hospitals experiencing shortages of certain blood types.

2

Why

Because delays in obtaining the required blood type could cost the patient their life, and because the current blood bank inventory is managed in a digitally inflexible manner with the community.

3

Where

Inside emergency rooms, blood banks, and through random groups on social media

4

What

The absence of a smart and rapid link between the location of immediate blood need (the hospital) and a geographically nearby qualified donor

5

When

In critical cases and accidents, emergency surgeries, and when there is a sudden shortage in the blood bank's reserves.

KEY ATTRIBUTES

1

Speed & Efficiency

Very few steps to file or accept a distress call (avoid lengthy procedures and numerous fields in emergencies)

2

Trust & Reliability

Comfortable interfaces give the user a feeling that the data is official and reliable from real hospitals to ensure no tampering

3

High Visibility

Use clear colors (red for crisis, green for safety) and clear, easy-to-read fonts under pressure or in low light.

4

Gamification & Empathy

A friendly visual style on the rewards screen avoids the gloom of a medical setting and encourages continued giving.

THANK YOU
